## Introduction

This section contains descriptions of a variety of aeration devices for small to large-scale application. A motor-and-blower unit is available to fabricators of individual home aerobic units for under \$200. On-site fabrication of individual home aerobic units in accordance with plans obtained from the manufacturer might be explored by projects which need many individual home units.\*

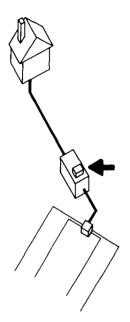

Two brands of helical flow aerators which are intended for use in oxidation ponds (lagoons) or large tanks are included. They operate as airlifts (with air injected at the bottom) which employ integral (static) turning vanes to induce flow conditions favorable to aeration. Inasmuch as the units are fixed in place and kept underwater, they are not likely to be targets of vandalism. Since all of the moving parts are contained in the shore-based air compressors which supply the mixers by hose lines, maintenance can be simplified over aeration systems which operate on or in the pond.

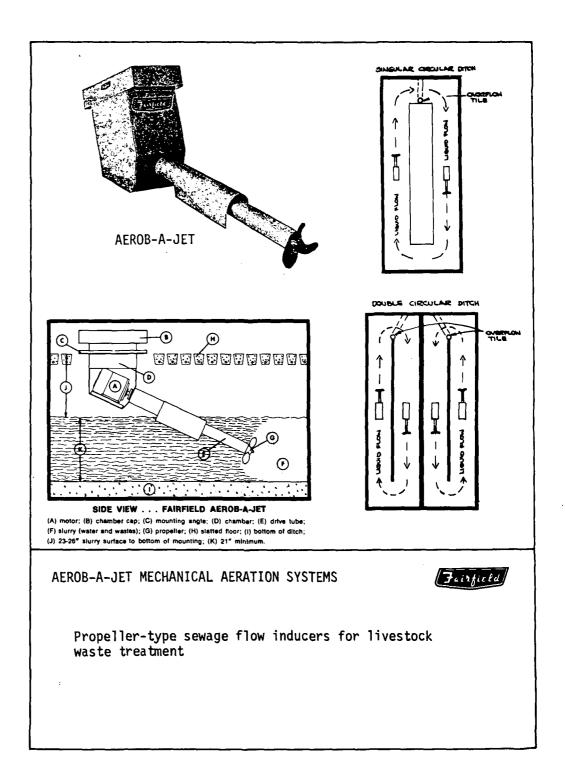

A newly-engineered floating aerator is also described. Among its virtues is the fact that no permanent installation is required other than the anchoring of mooring cables and the provision of a weatherproof and waterproof electrical line. Since the aerator and motor are submerged, the unit is also relatively immune to vandalism and surface icing, and the submerged center of gravity lends stability.

\*Just such an aerobic system, fabricated on-site with cinderblock materials and waterproofing, was observed by one of the authors on a visit to the Appalachian Environmental Health Demonstration Project, 108 South Kentucky Avenue, Corbin, Kentucky 40701. As far as a visual check could determine, the unit was working properly after over a year of service. The mixed liquor in the aeration chamber was brown, with no noticeable odor.

#### **Disinfection Devices** Introduction

Advance Chlorinators-Mounted, In-Line Chlorinators, 264 Capital Control Co. Sanuril-Pellet Feed Chlorinator, 266 Diamond Shamrock Corporation F & P Chlorinators-Mounted, In-Line Chlorinators, 268 Fisher & Porter Co. Ozone Generators-Ozonators-Corona Generators, 270 W. R. Grace and Co. Honeywell Chlorinators-Mounted, In-Line Chlorinators, 272 Honeywell Industrial Division Ultra-Dynamics Purifiers—Ultra-Violet Disinfection Unit, 274 Ultra-Dynamics Corporation

Even with properly operating equipment, present standards and practices for water treatment do not assure complete disinfection.\* When disinfection devices are improperly adjusted or when they are subject to malfunctions, the likelihood of their passing disease-causing organisms on to the receiving medium increases significantly.

The development of effective and highly reliable disinfection units is of great priority.

A variety of disinfection devices which can be used for disinfecting wastewater are described in this section. The most widely used method of disinfection is chlorination. Chlorine can be introduced in the gaseous state, as a solution of hypochlorite (house-hold bleach, for example), and as solid hypochlorite or other chemical compounds of chlorine. Whatever the form of introduction, the approach is to provide enough chlorine so that all organisms and substances that combine with chlorine will combine completely. An indication of the presumed sufficiency of the chlorination is a residual of free chlorine.

Chlorination takes time to kill organisms. Systems are designed such that the product of residual chlorine concentration and the chlorine-effluent contact time will equal a designated value which depends on the temperature and pH (alkalinity or acidity) of the water. Several chlorinators are described in this section.

Ozone,  $O_{3}$ , is a powerful agent for disinfection. Ozone can be created from oxygen gas by passing air through an electric discharge or through intense ultraviolet radiation of proper wavelengths. Ozone rich air is bubbled through the effluent, and as in the case of chlorine, it disinfects by oxidizing vital organic compounds which are constituents of microorganisms.

Ultraviolet radiation as well as ionizing radiation from other sources such as radioactive isotopes can be used to kill microorganisms. The ionizing radiation breaks apart key molecules which contain the basic information the cell needs in order to function. The completeness of kill depends on the wavelength and the intensity and duration of the radiation, as well as the amount of material (glass, water, for example) it must penetrate. Ionizing radiation units have been developed for municipal plants, but they are not generally available for small rural systems.

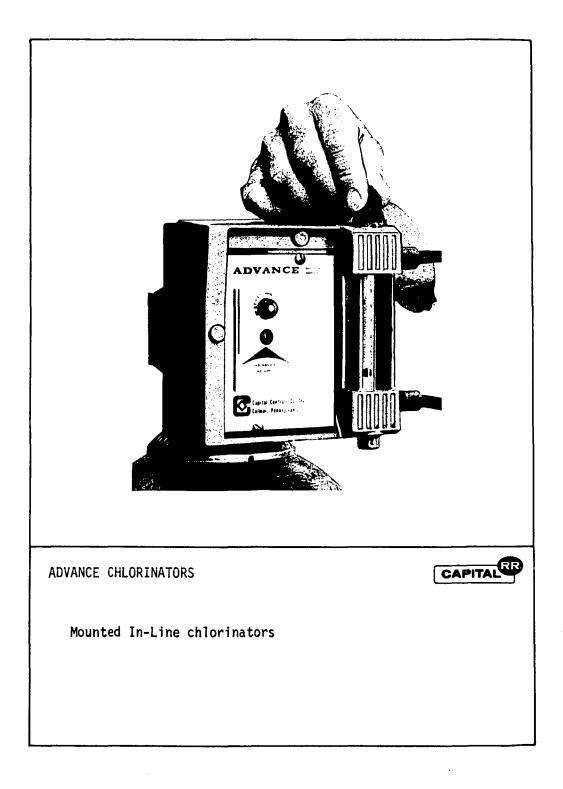

Pasteurization, or the killing of microorganisms contained in a liquid medium with prolonged application of heat, is another method of disinfection which may be especially

<sup>\*</sup>The Washington Post reported contaminated drinking water in two Massachusetts cities with drinkingwater treatment systems which "are not merely 'good' but of higher quality than those used for 'most of our waters' in the United States." [38] The water supplies of the two cities were found to contain viruses that cause disease in man. The discovery was said to be the first of its kind for properly treated water in the U.S.—previously discovered viruses in treated water supplies had been traced to malfunctions in treatment procedures.

263

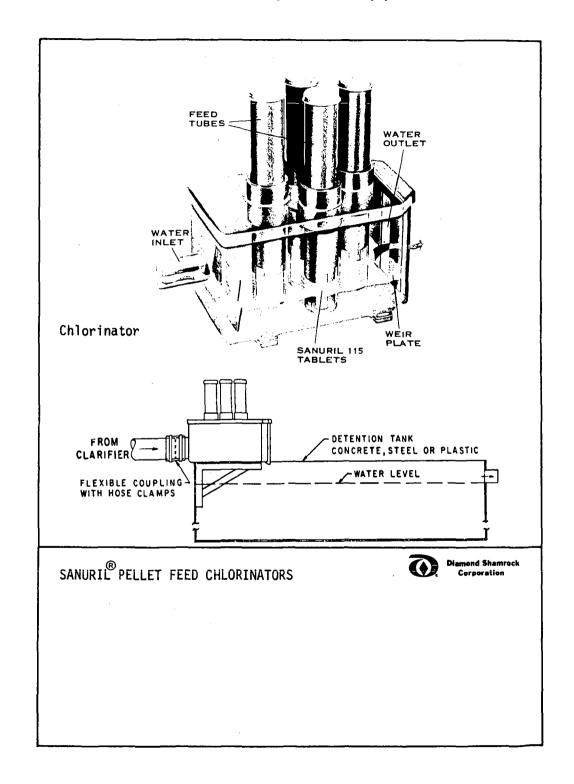

applicable to on-site treatment plants. By efficient design, energy can be transferred from the pasteurized treated effluent to the influent or to the mixed liquor through the use of heat exchangers. The resultant rise in temperature will generally speed up the processing of the sewage. One manufacturer plans to make pasteurization units for small plants available in the near future.
